

## Electric field

$$E = F_e / q \text{ definition}$$

around point charges,  $Q$

$$E = KQ / r^2$$

if there are multiple charges, you vector sum all the electric fields

$$E = \text{vector sum of } E_1 + E_2 \dots$$

The electric field at a point,  $r$  from  $Q$ .

In a uniform field, don't use that equation, the field is created by charge on parallel plates. Just use  $E = F_e / q$  or  $E = V / d$   $V$  is voltage between the plates and  $d$  is the distance between the plates (derived next class)

Field lines rules:

line represents the direction of force on a small positive test charge,  $q$ .

$E$  at point  $p$  shows the direction of force if there

was a positive charge,  $q$  at that point.

E lines go from positive to the negative  
the density of lines corresponds to the strength of the field

Lines never cross

always perpendicular to conducting surfaces and equipotential lines (next class)

lines are uniform distribution and parallel between infinite charged parallel plates

eg. draw the field lines around

a) dipole

b) two equal positive charges

c)  $Q_1 = -3.0\text{C}$  and  $Q_2 = -1.0\text{C}$  4.0 cm apart  
calculate the E field at the midpoint between them, and 2.0 cm above the midpoint

d) two parallel plates with opposite charges

e) calculations  $E_1 = \frac{kQ_1}{r^2}$

$E_1 = 8.99E9 \times 3 / (0.02^2) = 6.7425E13 \text{ N/C}$   
 usually measure static charge in micro coulombs

$E_2 = 8.99E9 \times 1 / (0.02^2) = 2.2475E13 \text{ N/C}$

$$E_{\text{resultant}} = E_1 - E_2 \text{ (opposite direction)}$$

$$6.7425 \times 10^{13} - 2.2475 \times 10^{13} = 4.495 \times 10^{13}$$

$4.5 \times 10^{13} \text{ N/C}$  towards  $Q_1$

at point p 2cm above the midpoint

$$E_1 = 8.99 \times 10^9 \times 3 / (0.02^2 + 0.02^2) = 3.3712 \times 10^{13} \text{ N/C}$$

$$E_2 = 8.99 \times 10^9 \times 1 / (0.02^2 + 0.02^2) = 1.1237 \times 10^{13}$$

$$E_r = \sqrt{(3.3712 \times 10^{13})^2 + (1.1237 \times 10^{13})^2} = 3.55354627520172 \times 10^{13}$$

$$3.55 \times 10^{13} \text{ N/C}$$

$$\theta = \text{Atan}(1.1237 \times 10^{13} / 3.3712 \times 10^{13}) = 18.43443895151597$$

$$18.43443895151597 + 45 = 63.43443895151598$$

So the electric field 2 cm above the midpoint would be  $3.55 \times 10^{13} \text{ N/C}$   $63^\circ$  below the horizontal towards the  $-3\text{C}$  charge
